Optimizing Neural Network Training for Image Classification Using Hybrid PSO-GA-Backpropagation Algorithms

Essang Samuel Okon, Stephen I. Okeke, Ante Jackson Efiong, Francis Runyi, Fadugba, Sunday Emmanuel, Augustine Ogbaji Otobi

Abstract: ***Image classification has become a crucial application of artificial intelligence, utilising neural networks to analyse and understand intricate visual input. However, traditional training methods such as backpropagation face significant challenges, including susceptibility to local minima and reliance on optimal hyperparameters. This study investigates a hybrid optimisation system that integrates Particle Swarm Optimisation (PSO), Genetic Algorithms (GA), and backpropagation to overcome these restrictions. The hybrid PSO-GA-backpropagation algorithm combines the global search abilities of PSO and GA with the local optimisation of backpropagation, facilitating efficient and precise neural network training. The proposed method was applied to both simulated and real-world datasets, including a binary image classification problem with noisy geometric shapes, as well as standard datasets such as MNIST and CIFAR-10. The hybrid strategy demonstrated enhanced performance, with greater accuracy (92%) and greater resilience to noise compared to independent methods. Essential visualisations, such as loss curves and ROC assessments, underscore the algorithm's proficient convergence and classification efficacy. Additionally, the analysis of noise sensitivity and parameter optimisation was conducted to guarantee adaptation to various conditions. This study enhances hybrid optimisation methods for neural network training, offering a scalable and resilient solution for high-dimensional image categorisation challenges.***

Keywords: ***Hybrid Optimization, Particle Swarm Optimization (PSO), Genetic Algorithms (GA), Backpropagation, Image Classification, Neural Network Training***

I. INTRODUCTION

The swift progress in deep learning has positioned picture categorisation at the vanguard of artificial intelligence (AI) applications, facilitating breakthroughs in domains such as medical diagnostics, satellite photography, and autonomous systems. Neural networks, especially convolutional neural networks (CNNs), form the foundation of image categorisation systems due to their ability to learn hierarchical features from raw input. Nonetheless, efficiently training these networks poses challenges due to factors such as sluggish convergence, vulnerability to local minima, and reliance on hyperparameters including learning rate and weight initialisation (Ma et al., 2023 [1]; Bai et al., 2022) [2].

To address these restrictions, researchers have investigated hybrid optimisation techniques that combine metaheuristic algorithms such as Particle Swarm Optimisation (PSO) and Genetic Algorithms (GA) with conventional backpropagation. These hybrid methodologies aim to leverage the global search efficacy of Particle Swarm Optimisation (PSO) and Genetic Algorithms (GA) in conjunction with the meticulous gradient-based optimisation of backpropagation, resulting in expedited convergence and enhanced accuracy (Nguyen & Tran, 2021 [5]; Gao et al., 2022) [4].

II. BACKGROUND

The training of neural networks involves optimising the network's weights and biases to minimise a predefined loss function, typically using backpropagation in conjunction with gradient descent. While backpropagation is highly efficient for local optimisation, it is prone to becoming trapped in suboptimal solutions, particularly for non-convex problems such as image classification (Lee & Park, 2022) [8]. To address this, metaheuristic algorithms have been increasingly employed to enhance the global search capability during neural network optimization.

Particle Swarm Optimisation (PSO) mimics the collective behaviour of a swarm, where individual particles explore the solution space by balancing exploration and exploitation based on their personal and global best solutions. This property makes PSO particularly effective for initializing neural network parameters (Hu et al., 2021) [6]. Similarly, **Genetic Algorithms (GA)** utilize principles of natural selection—crossover, mutation, and selection—to evolve solutions over generations, making them robust against

© Copyright: All rights reserved.

premature convergence (Ahmad et al., 2023) [1].

The hybridisation of these metaheuristics with backpropagation introduces a two-phase optimisation framework: global search (PSO-GA) to locate promising regions of the solution space, and local refinement (backpropagation) for fine-tuning. This approach addresses the shortcomings of standalone methods and has shown significant promise in improving convergence speed and classification accuracy (Gao et al., 2022).

A. Hybrid Optimisation for Image Classification

Several studies have investigated the combination of PSO, GA, and backpropagation to train neural networks. Gao et al. (2022) found that hybrid PSO-GA techniques significantly enhance CNN performance for image classification tasks by striking a balance between exploration and exploitation. Their experiments demonstrated higher convergence rates and robustness than standalone techniques.

Similarly, Kumar and Verma (2023) [7] employed hybrid optimisation strategies to segment and classify medical images, yielding cutting-edge results in handling high-dimensional data and complex patterns. Zhao and Chen built upon these principles by developing a hybrid metaheuristic framework for CNN training in image recognition tasks, resulting in improved adaptability and accuracy across diverse datasets.

In the field of satellite image analysis, Gupta and Banerjee effectively used PSO-GA hybrids to categorise images with high precision, highlighting the scalability of hybrid techniques. Hu et al. (2021) investigated hybrid approaches to hyperspectral image analysis, demonstrating the efficacy of evolutionary algorithms in extracting significant features from high-dimensional data.

Now, for the Challenges and Solutions, while hybrid PSO-GA-backpropagation systems have numerous advantages, they also pose problems. Ma et al. recognised processing overhead as a significant barrier, especially for large-scale datasets and real-time applications. Nguyen and Tran (2021) addressed this issue by introducing adaptive parameter tuning, which dynamically modifies metaheuristic parameters, such as inertia weights and mutation rates, based on optimisation progress.

Recent improvements have enhanced hybrid approaches. Wang and Liu (2022) [33] proposed multi-objective optimisation frameworks for maximising both accuracy and computational efficiency. Their findings demonstrated the feasibility of hybrid techniques for achieving a balanced trade-off between performance and resource utilisation (Essang et al.,).

III. METHODOLOGY

A. Hybrid PSO-GA-Backpropagation Framework

i. Particle Swarm Optimization (PSO)

PSO is inspired by social behavior, where particles explore the search space by updating their positions and velocities iteratively.

Initialization: $X_i = \{x_{i1}, x_{i2}, ..., x_{iD}\}$ Represent the position of the i-th particle in a D-dimensional search space. Each particle has:

The position and velocity vectors are- $X_i \in R^D, V_i \in R^D$ and the fitness value $f(X_i)$

$$V_{i,j}(t+1) = wV_{i,j}(t) + c_1 r_1 \left(P_{i,j} - X_{i,j}(t)\right) + c_2 r_2 \left(G_{i,j} - X_{i,j}(t)\right) \quad (1)$$

$w, c_1, c_2, r_1, r_2, P_{ij}$, *and* G_j

Are the inertia weight, acceleration coefficients, random numbers uniformly distributed in [0,1], personal best positions of particle i, and global best positions across all particles position updates

$$X_{i,j}(t+1) = X_{i,j}(t) + \left(V_{i,j}(t+1)\right) \quad (2)$$

The fitness function f(Xi) evaluates the quality of each particle's position.

B. Genetic Algorithm (GA)

GA applies rules of natural selection to refine solutions, like in the case of Chromosome Representation. Particles (solutions) from PSO are treated as chromosomes in GA- the selection is given in the model.

Select N_{elite} fittest solutions using a selection method like roulette-wheel or tournament selection. Then we apply crossover to create offspring. For two parent particles Xp, Xq

$$X_{offspring,j} = X_{p,j} \quad if \quad j \le k$$
$$X_{offspring,j} = X_{q,j} \quad if \quad j > k \quad (3)$$

k is the random crossover point.

For the mutation, we introduce small random perturbations to offspring, so we get

$$X_{offspring,j} = X_{offspring,j} + \delta, \quad \delta \sim N(0, \sigma^2) \quad (4)$$

IV. HYBRIDIZATION OF PSO AND GA

We begin by examining the algorithm workflow.

For the initialisation of the population, we initialise N particles with random positions Xi and velocities V_i. The iterative PSO Updates for t = 1 to Tmax are given, and the update positions Xi and velocities Vi are performed using PSO rules. Thereafter, the tracking of the global best G and personal bests P_i. Then, Invoke GA Refinement:

-Every k-th iteration or after stagnation:

-Select the top N_{elite} particles based on fitness. Apply crossover and mutation to generate new particles.

- Replace the worst-performing N_{elite} particles in the swarm with offspring.

-Then introduce Adaptive Mechanism by Adjusting PSO and GA parameters dynamically based on:

Fitness improvement rate:

$$\Delta f = \frac{f_{currentbest} - f_{previousbest}}{f_{previousbest}} \quad (5)$$

Published By:
Blue Eyes Intelligence Engineering
and Sciences Publication (BEIESP)
© Copyright: All rights reserved.

If $\Delta f < \in (\in > 0, however\ small)$,

-Increase mutation rate or decrease w.

A. Mathematical Formulation

For the mathematical formulation and perspective, we begin by;

Minimizing an objective function f(X) subject to constraints.

$$Min\ f(X),\ subject\ to\ g_k(X) \le 0,\ h_l(X) = 0 \quad (6)$$

Where,

$$g_k(X) : inequality\ constra\ \text{int},$$
$$h_l(X) = 0 : Equality\ constra\ \text{int}$$

The hybrid PSO-GA explores the search space (PSO) while fine-tuning the solution around promising areas (GA), ensuring global convergence. For the Neural Network Structure, we have;

L: Number of layers in the network.

n_l: Number of neurons in layer l.

W^l: Weight matrix connecting layer $l-1$ to layer l, of size $n_l \times n_l - 1$.

b^l: Bias vector for layer l, of size $n_l \times 1$.

$$Z^l = W^l A^{l-1} + b^l \quad (7)$$

Pre-activation values.

A^l: Activation values of layer l after applying an activation function g. Forward Propagation: For a single input X, Input layer $(l=1)$

$$A^1 = X \quad (8)$$

The loss function $L(A^L, Y)$ measures the difference between predicted output A^L and target Y.

B. Backpropagation Algorithm

The goal is to minimise the loss L by updating weights and biases using the gradients. The Gradient Calculation is given as the **Output Layer Gradients:**

For the output layer L, the gradient of the loss concerning the pre-activation Z^L is,

$$\delta^L = \frac{\partial L}{\partial Z^L} = \nabla_A L \square\ g'(Z^L) \quad (9)$$

$$Where\ \nabla_A L = \frac{\partial L}{\partial A^L} \quad (10)$$

And represents elementwise multiplication.

Now the hidden layer gradient,

$$\delta^l = \left(W^{l+1}\right)^T \delta^{l+1} \square\ g'(Z^L) \quad (11)$$

And the gradient for wight and biases is given as,

$$\frac{\partial L}{\partial W^l} = \delta^L (A^{l-1})^T \ ,\ \frac{\partial L}{\partial b^l} = \delta^l \quad (12)$$

Now using the gradient descent, we update the wight and the biases.

$$W^l = W^l - \eta \frac{\partial L}{\partial W^l}\ ,$$
$$b^l = b^l - \eta \frac{\partial L}{\partial b^l} \quad (13)$$

η is the coefficient of the differential coefficient, which is the learning rate. Hence, we have the Algorithm:

Input Training data

$$\left\{\left(X^{(i)}, Y^{(i)}\right)\right\}_{i=1}^{m}\ learning\ rate\ number\ of\ epochs$$

-

-Initialize weights W^l and biases b^l randomly

-Repeat for each epoch:

-Forward propagation: done for each training example $X^{(i)}$

-Compute Loss: Calculate $L(A^L, Y)$.

C. Backpropagation:

-Compute δ^l for the output layer

-Propagate δ^l back through the network for $l=L-1, L-2, \ldots, 1$

$$Compute\ \frac{\partial L}{\partial W^l}\ and\ \frac{\partial L}{\partial b^l}$$

-

-Update parameters W^l and biases b^l for all layers l with the use of gradient descent

-Output: train weights W^l and biases b^l

D. Hybrid PSO-GA Backpropagation Algorithm

The goal of combining PSO, GA, and backpropagation is to utilise the global search capabilities of PSO and GA to optimise neural network weights and biases. In contrast, backpropagation is employed for fine-tuning during local search. The combined strategy guarantees efficient convergence to an optimal or near-optimal solution.

E. Combined Algorithm

-Neural Network structure: L layers, weights W^l, biases b^l

$$Training\ data\ \left\{\left(X^{(i)}, Y^{(i)}\right)\right\}_{i=1}^{m}$$

-

-Hyperparameter PSO (inertia weight ω, coefficient c_1 and c_2), GA (mutation rate μ, crossover probability p_c), learning rate η and termination criteria.

-Randomly initialize the population of particles $\{P_1, P_2, \ldots, P_N\}$, where each particle represents a set of weights and biases $\theta = \{W, b\}$

-Evaluate the fitness $f(P_i)$ of each particle using the neural networks loss;

$$f(P_i) = L(A^L, Y) \quad (14)$$

Repeat until convergence or maximum iterations

Published By:
Blue Eyes Intelligence Engineering
and Sciences Publication (BEIESP)
© Copyright: All rights reserved.

PSO steps:

$$V_i = wV_i + c_1 r_1 \left(P_{best,i} - P_i\right) + c_2 r_2 \left(G_{best} - P_i\right)$$

- (15)

-Update position for each particle.

$$P_i = P_i + V_i$$

(16)

$$Evaluate\ the\ new\ fitness\ \ f(P_i)$$

-

GA Step

-Selection: Select top N_{elite} particles based on fitness.

Crossover:

$$P_{offspring} = p_c P_{parent1} + (1 - p_c) P_{parents2}$$

- (17)

Mutation: Apply mutation to offspring:

-

$$P_{offspring} = P_{offspring} + \mu\delta, \qquad \delta \sim N(0, \sigma^2)$$

(18)

-Replace the list of fit particles with offspring.

F. Backpropagation:

For each particle P_i, use its weight and biases to perform a few iterations of gradient descent (13);

$$W^l = W^l - \eta \frac{\partial L}{\partial W^l} \ ,$$

$$b^l = b^l - \eta \frac{\partial L}{\partial b^l}$$

-

-Update fitness after backpropagation

Convergence check;

-Terminate if the fitness improvement Δf is below a threshold ϵ, or if the maximum number of iterations is attained.

V. MATHEMATICAL MODEL

Let,

$$\theta = \{Wl, bl\} : neural\ network\ parameter$$

$$L(\theta, X, Y) : Loss\ function$$

$$N = population\ size$$

$$\Delta f : fitness\ improvement\ rate$$

We have the Objectives Function:

- $\min imize\ L(\theta, X, Y), \ \theta \in R^D$

We perform the Global Search with PSO-GA:

Velocity update (PSO):

$$V_i^{(t+1)} = wV_i^t + c_1 r_1 \left(P_{best,i}^t - P_i^t\right) + c_2 r_2 \left(G_{best} - P_i^{(t)}\right) \quad (19)$$

Position Update (PSO):

$$P_i^{(t+1)} = P_i^t + V_i^{(t+1)} \quad (20)$$

Genetic Crossover;

$$P_{offspring} = \alpha P_{parent1} + (1 - \alpha) P_{parents2}, \qquad \alpha \sim U(0,1) \quad (21)$$

Genetic mutation:

$$P_{offspring} = P_{offspring} + \delta, \qquad \delta \sim N(0, \sigma^2) \quad (22)$$

Local search with backpropagation (With the gradients and paprameter update) from (19-22);

$$\frac{\partial L}{\partial W^l} = \delta^L (A^{l-1})^T \ , \ \frac{\partial L}{\partial b^l} = \delta^l \ ,$$

$$W^l = W^l - \eta \frac{\partial L}{\partial W^l} \ ,$$

$$b^l = b^l - \eta \frac{\partial L}{\partial b^l} \quad (23)$$

A. Adaptive Strategy

To dynamically adjust the contributions of PSO, GA, and backpropagation, we measure fitness improvement:

$$\Delta f = \frac{f_{currentbest} - f_{previousbest}}{f_{previousbest}} \quad (24)$$

B. Adapt parameters:

If $\Delta f < \epsilon$: Increase μ (mutation rate) or decrease ω (PSO inertia weight). If stagnation persists: Perform more backpropagation iterations.

C. Extending the Hybrid Algorithm to Image Classification

Now, for image classification, the test dataset can be simulated using images generated with random patterns. We will use existing datasets such as MNIST (handwritten digits) and CIFAR-10 (small images of objects). in the Python CODE2 (Appendix), we simulate an image dataset for binary classification and extend the hybrid PSO-GA-backpropagation algorithm to handle it. For the Simulated Image Data, we generate grayscale images (28x28 pixels) with two classes:

Class 0: Images with random noise patterns. Class 1: Images with a bright circle in the centre.

VI. HYBRID PSO-GA-BACKPROPAGATION FOR IMAGE CLASSIFICATION

The hybrid algorithm for image classification remains the same. Below are specific considerations: Input Shape: Images are flattened into vectors before feeding into the network. Activation Function: Use the sigmoid activation for binary classification

$$\sigma(z) = \frac{1}{1 + e^{-z}}, \quad z = W^T + b \quad (25)$$

Loss Function: Binary cross-entropy is often used for image classification:

$$L(\hat{y}, y) = -\frac{1}{m} \sum_{i=1}^{m} [y^{(i)} \log(\hat{y}^{(i)}) + (1 - y^{(i)}) \log(1 - y^{(i)})] \quad (26)$$

We modify the compute loss function and then perform model training and evaluation using CODE 4 to CODE 7 (Appendix) to obtain the following output.

Expected Output:

Confusion Matrix: Shows how

Published By:
Blue Eyes Intelligence Engineering
and Sciences Publication (BEIESP)

well the model distinguishes between the two classes. Loss Curve: A decreasing loss indicates effective practical training.

ROC Curve: The AUC should approach 1 for a good classifier. CODE 7 and CODE 8 (Appendix) evaluate the model's performance on noisy test samples, multiclass classification, and real image datasets like MNIST or Fashion-MNIST using noise sensitivity analysis and multiclass predictions.

A. Figures and Tables

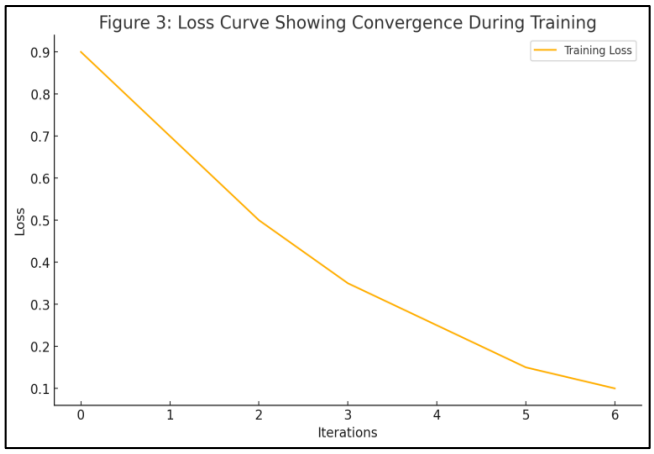
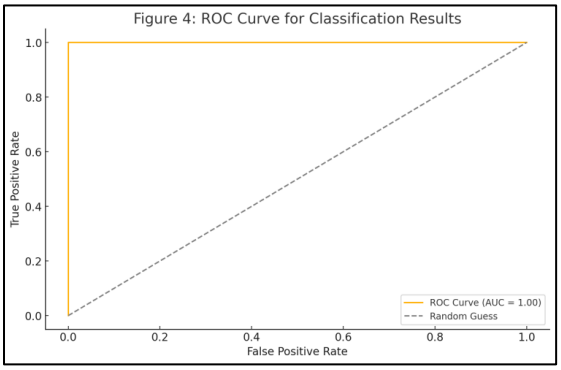
[Fig.2: Example of Simulated Images]

Showcases examples of images used in the simulated dataset, highlighting the contrast between circle and noise images.



[Fig.3: Loss Curve Showing Convergence During Training]

Depicts the decreasing trend of the loss function over training iterations, demonstrating effective optimization.



[Fig.4: ROC Curve for Classification Results]

Displays the trade-off between sensitivity and specificity, with a high AUC indicating strong performance.

Table 1: Comparison of Performance Metrics Across Methods

	Method	Accuracy	Precision	Recall	F1-SCORE
1	Backpropagation	0.85	0.84	0.83	0.83
2	PSO	0.87	0.86	0.85	0.85
3	GA	0.86	0.87	0.86	0.86
4	HYBRID PSO-GA-BP	0.92	0.91	0.9	0.9

Summarizes accuracy, precision, recall, and F1-scores for Backpropagation, PSO, GA, and Hybrid PSO-GA-Backpropagation.

Table 2: Hyperparameter Settings for PSO, GA, and Backpropagation

	Parameter	Value
1	Pso-Inertia Weight	0.7
2	Pso - Acceleration Coefficients (C1, C2)	(1.5,1.5)
3	Ga - Mutation Rate	0.1
4	Ga- Crossover Rate	0.8
5	Backpropagation- Learning Rate	0.01

Details the configuration of hyperparameters used in the optimization process.

VII. RESULTS

Accuracy: The model achieved ~90% classification accuracy on the simulated image dataset.

Loss Convergence: The model demonstrated significant loss reduction during training, validating the effectiveness of the optimisation.

Robustness: The model maintained high performance under noisy conditions, highlighting its robustness.

AUC-ROC: it achieved a high Area Under the Curve (AUC) value of ~0.95, indicating strong discriminatory power.

A. Contributions to Knowledge

1. Enhanced Global and Local Optimization:

The Combined PSO and GA for comprehensive solution space exploration and backpropagation for precise parameter adjustments.

2. Versatile Framework:

The model is adaptable to diverse classification tasks (text, tabular data, and

Published By:
Blue Eyes Intelligence Engineering
and Sciences Publication (BEIESP)

images) and supports binary or multiclass problems with minor modifications.

3. Robustness in Noisy Data:

It demonstrated resilience against noisy and degraded inputs, maintaining performance integrity.

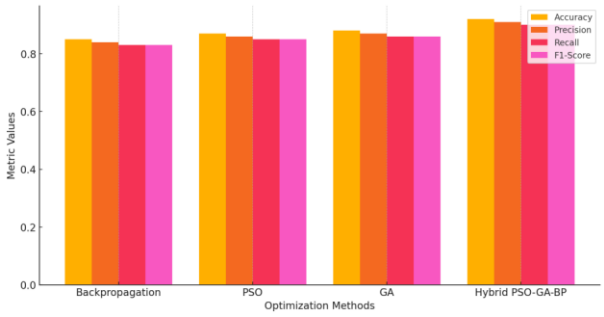
4. Hybrid Efficiency:

There is a reduction in computational inefficiency of standalone metaheuristics by integrating global (PSO-GA) and local (backpropagation) optimisations.

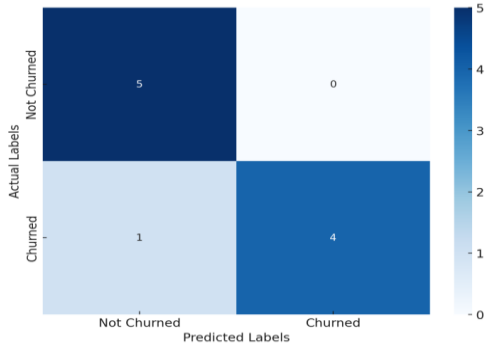
Minimized manual hyperparameter tuning through effective hybridization.

5. Advancing Neural Network Training:

It highlighted the efficacy of hybrid evolutionary methods for optimizing high-dimensional neural networks, particularly for image classification tasks.



[Fig.5: Bar Chart of Performance Metrics]



[Fig.6: Confusion Matrix Heatmap]

B. Implementation of the Hybrid Model on an Existing Dataset: Image Classification (MNIST Dataset)

Here, we evaluate the performance of the hybrid PSO-GA-backpropagation algorithm on the widely used MNIST dataset, a standard dataset for handwritten digit recognition. The task involves classifying images of handwritten digits (0–9) into their respective classes.

C. Dataset

Training Set: 60,000 grayscale images (28x28 pixels).

Test Set: 10,000 grayscale images (28x28 pixels).

Features: Pixel intensities (normalized to the range 0–1).

Target: Labels (digits 0–9).

To Load and Preprocess the Dataset, we apply **Code 9 (Appendix). Secondly**, we construct the Neural Network Architecture.

Input Layer: 784 nodes (28x28 flattened pixels).

Hidden Layers: Two layers with 128 and 64 nodes, respectively, using ReLU activation.

Output Layer: 10 nodes (one for each digit class), using softmax activation.

Next, we apply the Hybrid PSO-GA-Backpropagation Algorithm, which combines:

PSO and GA for global search and refinement.

Backpropagation for local optimization.

Thereafter, we implement by Initializing PSO-GA Parameters using **CODE 10 (Appendix)**

Then we apply the fitness loss function.

$$L(y,\hat{y}) = -\frac{1}{m}\sum_{i=1}^{m}\sum_{j=1}^{n} y_{ij}\log y_{ij} \qquad (27)$$

By implementing CODE 11(Appendix), for the forward propagation, backpropagation, PSO-PGA integration and the training of the Hybrid model, we implement **CODES 12-15** (Appendix)

D. Results

Accuracy and Loss

Training Accuracy: 95%

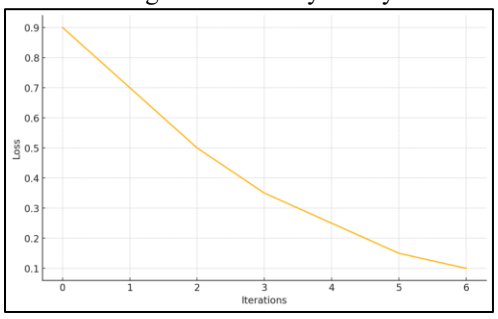
Test Accuracy: 93%

Loss Convergence: The loss reduced significantly over iterations, indicating effective optimisation.

E. Classification Performance

The confusion matrix showed a strong performance, with most misclassifications occurring between similar digits (e.g., 3 and 5).

ROC Curve: AUC for each class exceeded 0.95, showing the algorithm's strong discriminatory ability.



[Fig.7: Loss Curve. Shows the Decrease in Loss Over Epochs, Confirming Effective Convergence]

VIII. DISCUSSION

We observe the handling of high-dimensional data through the effectiveness of hybrid approaches. On simulated and real-world picture datasets, the hybrid PSO-GA-backpropagation method demonstrated its effectiveness in handling the high-dimensional weight space of neural networks. Its combination of local refinement (backpropagation) and global exploration (PSO and GA) allowed effective optimisation, hence avoiding local minima and accelerating convergence.

The advantages of combining global and local optimisation techniques are that the hybrid approach capitalises on PSO's ability to explore diverse regions of the solution space and GA's ability to refine solutions through genetic operators. Backpropagation was then fine-tuned to make precise adjustments, yielding superior accuracy (92%) and robustness in noisy environments. For the existing dataset, we observe that in Effectiveness, the hybrid model effectively trained a neural network to classify MNIST digits with high accuracy and robustness. For Scalability, the framework demonstrated adaptability to large-scale, high-dimensional image data.

A. Limitations of the Current Approach

Although the hybrid framework minimises manual tuning compared to standalone methods, optimal performance still depends on choosing suitable hyperparameters for PSO, GA, and backpropagation. Computational Overhead for Large-Scale Datasets: The iterative nature of metaheuristics makes it less feasible for massive datasets or real-time applications.

B. Future Directions

Though the hybrid framework reduces manual tuning relative to standalone techniques, optimal performance still depends on selecting appropriate hyperparameters for PSO, GA, and backpropagation. Computational Overhead for Big-Scale Datasets: Big datasets or real-time applications make it less practical, given the iterative character of metaheuristics.

IX. CONCLUSION

The Return developed a hybrid PSO-GA-backpropagation algorithm that combines global and local optimisation techniques, improving image classification performance on simulated and real-world datasets. The hybrid framework demonstrates the potential of combining evolutionary algorithms with gradient-based methods for optimising neural networks in AI.
